# ***Why are carbon nanotubes technologically important?***

- With walls parallel to the filament axis, several favourable properties are inherited from intra-plane graphite:
  - High electrical conductivity
  - High thermal conductivity
  - High mechanical strength and modulus
  - Very few dangling bonds or edges – inert
  - Covalently bonded – no electromigration
  - 1-D single wall tubes can be metallic or semi conducting and exhibit quantum effects.

Ceramic & Materials  
Engineering

# *Historical Background*

- Attributed mainly to Iijima [Nature 354, 56 (1991)] who observed “**microtubules of graphitic carbon**” in the cathode deposit of arc discharge of graphite.

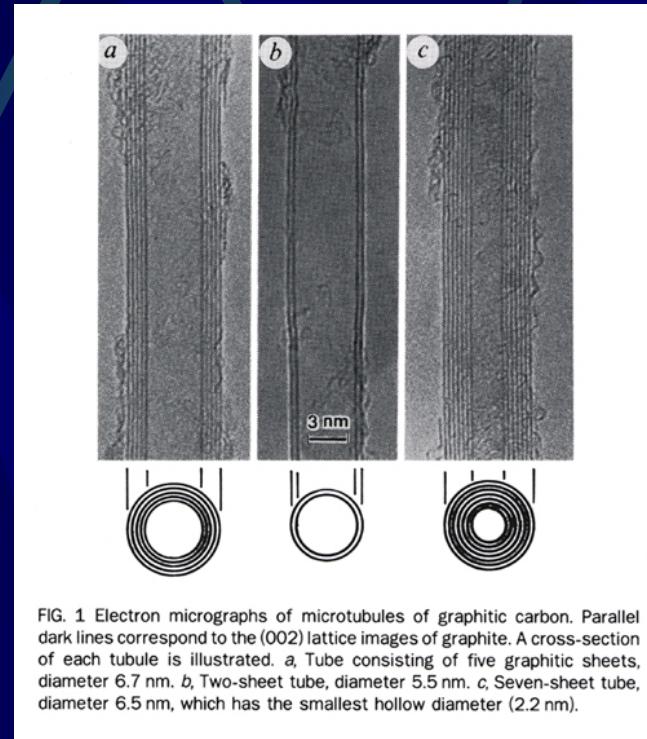

FIG. 1 Electron micrographs of microtubules of graphitic carbon. Parallel dark lines correspond to the (002) lattice images of graphite. A cross-section of each tubule is illustrated. a, Tube consisting of five graphitic sheets, diameter 6.7 nm. b, Two-sheet tube, diameter 5.5 nm. c, Seven-sheet tube, diameter 6.5 nm, which has the smallest hollow diameter (2.2 nm).

# ***Electronic Structure of SWNT***

- Single wall nanotubes can be semiconducting!

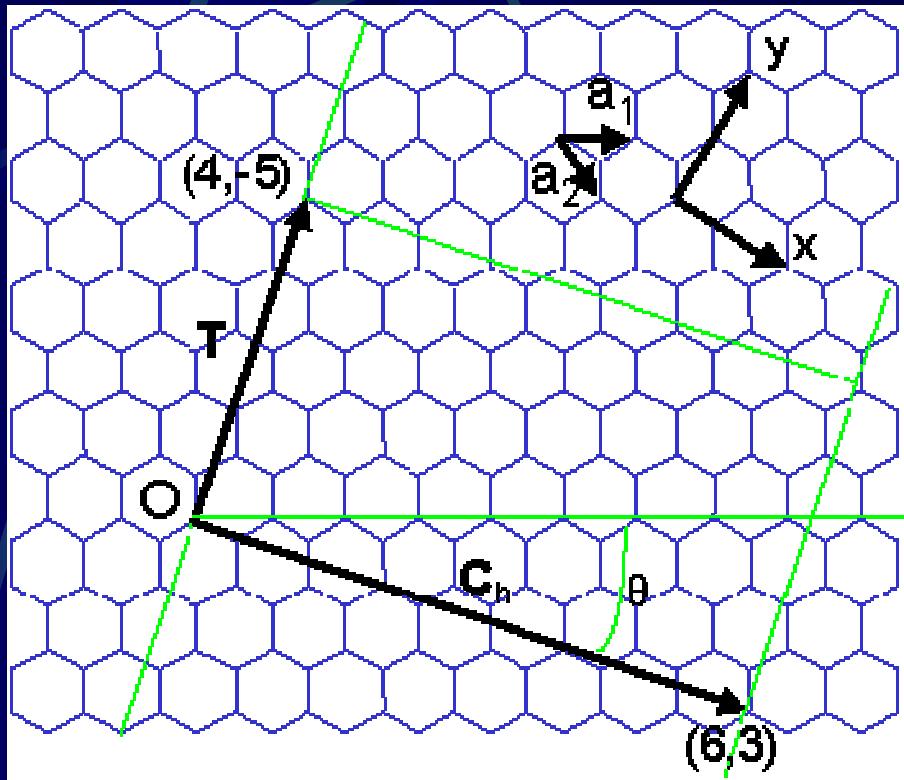

- It all depends on the angle of rolling and diameter of the nanotube.

Ceramic & Materials  
Engineering

# **Definition of Chiral Vectors**

$$\mathbf{C}_h = n\mathbf{a}_1 + m\mathbf{a}_2$$

$$|\mathbf{a}_1| = |\mathbf{a}_2| = \sqrt{3}a_{cc} = a$$

( $a$  is unit length)

$$\text{Length of } \mathbf{C}_h = \sqrt{3}a_{cc} (n^2 + mn + m^2)^{0.5}$$

$$\text{Hence, } d_t = \mathbf{C}_h/\pi$$

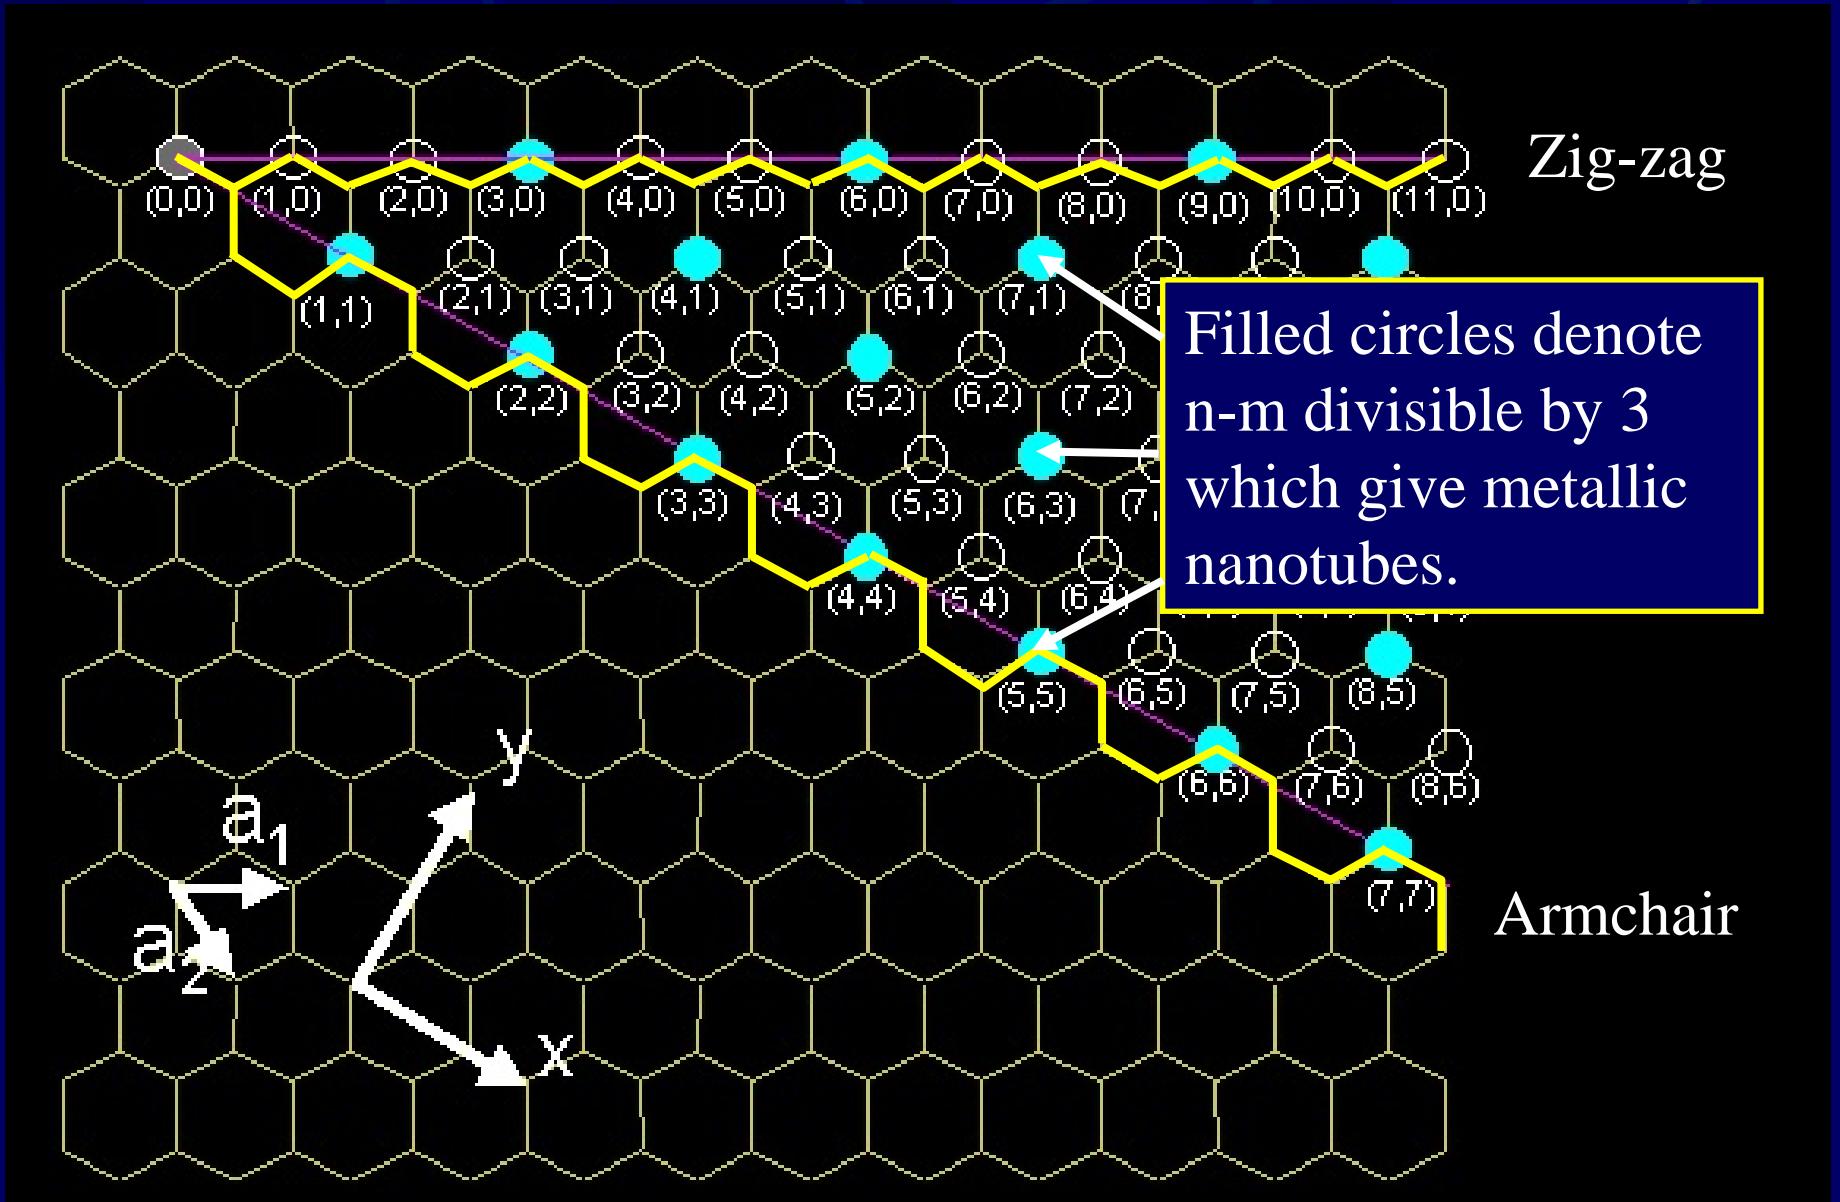

$$\text{Translational Vector } \mathbf{T} = [(2m+n)\mathbf{a}_1 - (2n+m)\mathbf{a}_2]/d$$

$$\text{Chiral Angle } \theta = \tan^{-1} [\sqrt{3}m/(m+2n)]$$

*- Growth and Field Emission  
Applications*

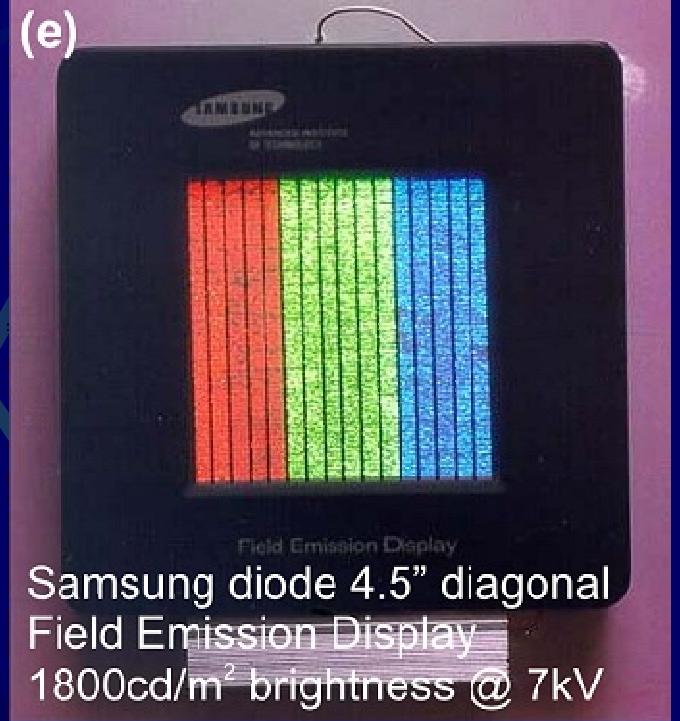

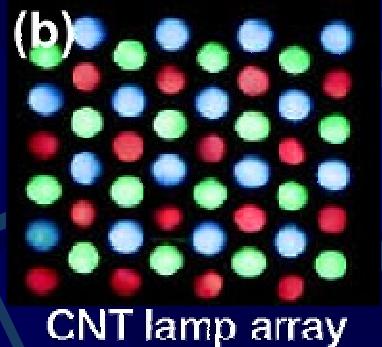

Ceramic & Materials  
Engineering

# Field Emission Applications We are Investigating

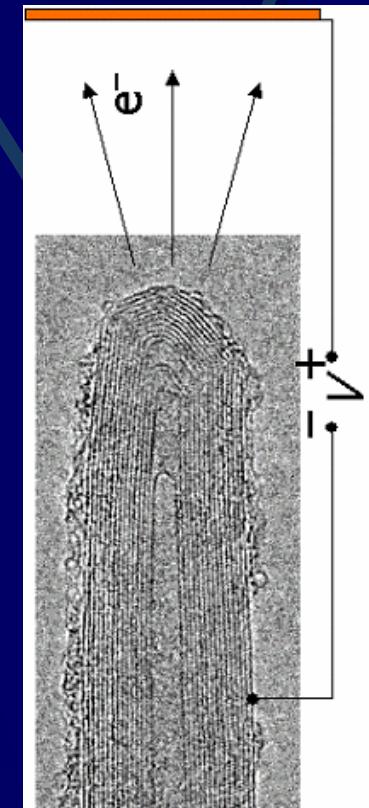

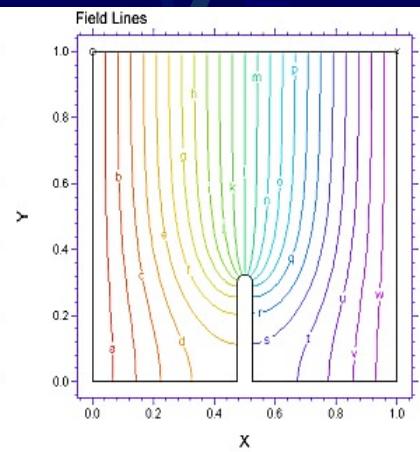

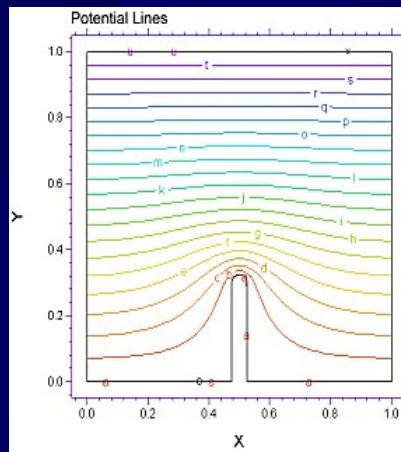

# *Field Emission Applications*

- CNT's are favourable as field emission electron sources because they have:
  - High aspect ratio
  - Small tip radius
  - High conductivity

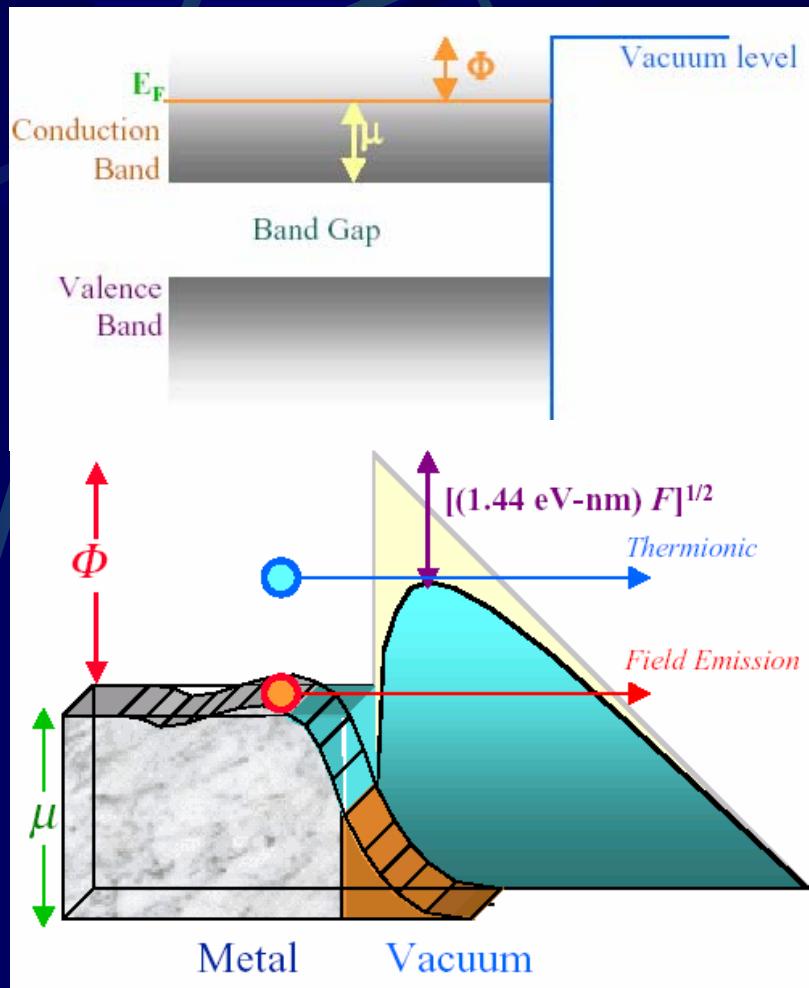

(NB. multiwall are non-semiconducting)

Ceramic & Materials  
Engineering

THE STATE UNIVERSITY OF NEW JERSEY  
**RUTGERS**

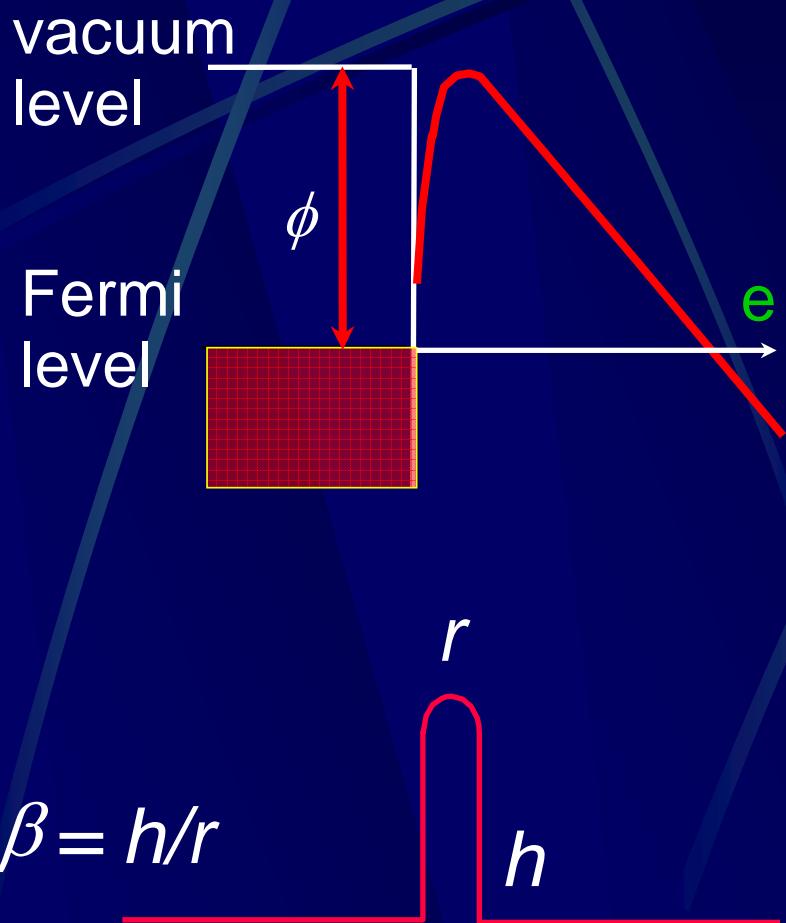

# Electron Emission

- Large density of electrons exist in the conduction band
- Very small fraction contribute to emission current
- Most energetic electrons lie several eV below vacuum level
- Either temperature or voltage required for emission

# What is Field Emission?

- Electron tunnelling from solids under high local field ( $10^8$  V/m)
- Fowler-Nordheim equation:
$$J = aF^2 \exp\left(-\frac{b\phi^{3/2}}{\beta F}\right)$$
- $\phi$  = barrier height
- Local field  $F_L = \beta F$
- Fowler-Nordheim plot,  $\ln(J/F^2) = c + d/F$
- Slope gives  $\phi^{3/2}/\beta$  *not*  $\phi$
